Day 5: Final Review and presentation

Summarization of the week's work

React Setup

For the React setup I had to download Node.js by going to its official website and downloading the version for my device. Then I also had to download React onto my code editor by going to Terminal and entering "npx create-react-app (then the name that you want the folder to be)". After doing these things you can start coding in the App.js file.

Routing

To implement routing I first had to have components to route connect the router to. So I had to create a folder named components and inside it have SignUp, Login and Home files. So then in the App I imported Route and Routes from react-router-dom and also imported from all the components. Then in the App I returned a Home tag to make sure what you input in the Home file is what appears in the App file. And then from the other components I imported Link from react-router-dom. Once I did all this the files were all routed.

HTML

In the HTML I used form, label, p, input and button tags to construct the content of the form. Each input had a different id, placeholder and value because they were all for different inputs.

CSS

While styling the form using CSS, I used different styles like font-size, font-family, margin and padding, height and width, color, background color and so many others. I used grid to move the form into one row to

make it look better. I also used grid to move the links into two rows to give the nav bar a better look.

Javascript

Using Javascript I was able to add form validation. This allows the website to reject any empty input field that the user submits by displaying an error message right under the input.
