

Name: Daniel Owie

Day 3: Form Validation

Validation Approach

Name

For the name I added an “if condition” that selects the input with an id of “name” that displays an error message that says enter your name when the name input doesn’t receive any value.

Email

For the email I added an “if condition” that selects the input with an id of “email” and rejects any email that doesn’t have an “@” sign or any email that doesn’t have a “.” sign and it displays an error message telling you to enter a valid email. It also displays an error message to enter a valid email.

Message

For the message I added an “if condition” that selects the input with an id of “message” that displays an error message that says “enter a valid message” when the message input doesn’t receive any value.

While adding form validation to the website I used the “getelementbyid” to select particular HTML tags to add their respective validations.

Issues encountered while adding form validation

While adding the form validation I encountered some issues like:

- The format needed to make the email validation work.
- Whether the isValid variable was meant to be true or false.
